Musculoskeletal ultrasound is a medical imaging technique used to visualize muscles, tendons, ligaments, joints, and soft tissues in the body's musculoskeletal system. It employs high-frequency sound waves to create real-time images, providing detailed information about the structure and function of these tissues. The ultrasound can be used for diagnostic imaging, guidance for procedures, and to monitor treatment response. Musculoskeletal ultrasound is a non-invasive valuable imaging tool in the evaluation and management of musculoskeletal disorders, offering real-time visualization, high-resolution images, and the ability to guide interventions with precision and accuracy.
